**Abstract:** Concentrations of serum IL-17 have been found at high levels in patients with AS. The role of serum IL-17 in ankylosing spondylitis (AS) was investigated through a meta-analysis undertaken to examine the correlation between AS disease activity and serum levels of IL-17 in AS compared to healthy controls and AS patients. Searches were performed in PubMed, ScienceDirect, Cochrane, and Lilacs databases for pertinent case-control studies using with the descriptors “Spondylitis, Ankylosing” and “Interleukin-17”. Expression in relation to healthy controls and correlation of IL-17 with BASDAI were plotted using Review Manager 5.3 software. Quality assessment of each eligible study used the Newcastle-Ottawa Scale. Thirteen case-control studies were selected for this meta-analysis and contained a pooled total of 752 AS patients and 607 healthy controls. Our main result revealed strikingly higher levels of serum IL-17 in AS patients, compared to healthy controls. Pooled mean difference 14.59, pooled risk ratios (RRs) with 95% confidence intervals (CIs) 7.73, 21.45;  $p < 0.00001$ . Serum IL-17 is highly expressed in serum of patients with AS and is related to disease activity. The treatment in use significantly influenced IL-17; however, we did not observe a significant difference in the expression of IL-17 in the treatment of patients taking anti-TNF, proving that it does not interfere in this pathway.

**Keywords:** Case control studies, expression IL-17, IL-23 and IL-17 pathway.

## INTRODUCTION

Ankylosing spondylitis (AS) is a chronic, inflammatory disease of the axial spine that can manifest with various clinical signs and symptoms (WENKER; QUINT, 2021; BRAUN, 2007). Current treatments aim to reduce symptoms, maintain spine flexibility and normal posture, and reduce limitations and

complications while maintaining work ability (WARD, 2016; SIEPER, 2019). The choice of treatment is based on remission or low disease activity accompanied by laboratory tests (SMOLEN et al., 2013). Non-steroidal anti-inflammatory drugs (NSAIDs), conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), biological DMARDs (bDMARDs), and physical activities are recommended (TAM et al., 2019).

Anti-TNFs play a key role in blocking AS, significantly reducing inflammation and bone destruction (TAUROG; CHHABRA; COLBERT, 2016). Current findings indicate participation in the IL-23/IL-17 pathway in the pathophysiology of AS (DEVECI, 2020; SHERLOCK; BUCKLEY; CUA, 2014; HREGGVIDSDOTTIR; NOORDENBOS; BAETEN, 2013). The IL-23/IL-23R complex in predisposed patients appears to induce the activation of signal transduction and transcription, with consequent proliferation and terminal differentiation of Th17 cells, resulting in the production of IL-17 (SHERLOCK; BUCKLEY; CUA, 2014; SMITH, COLBERT, 2014; ZUNIGA, 2013; MCGEACHY, 2009), TNF- $\alpha$  and other proinflammatory cytokines, and chemokines (YEREMENKO; PARAMARTA; BAETEN, 2014).

However, the literature diverges as to the expression of IL-17 in serum of EA patients, and this may be related to the treatment used by the patient. Hence, we undertook a meta-analysis to investigate how the disease activity and influence of the treatments used is related to the expression of IL-17 in the serum of EA patients.

## METHODOLOGY

Our report adheres to the Meta-analysis of Observational Studies in Epidemiology (MOOSE) Statements (STROUP et al. 2000). All enrolled studies satisfied the following

criteria: (1) all AS patients conformed to the New York clinical criteria for AS (van der LINDEN; VALKENBURG; CATS, 1984); (2) was a cross-sectional or case-control study; (3) reported the correlation between serum IL-17 levels and AS; (4) included AS patients as case group and healthy controls as control group and/or patients who are not active. The exclusion criteria were: (1) inconsistent diagnostic criteria for AS; (2) not case-control studies; and (3) incomplete original data.

The following electronic databases were consulted: Pubmed, ScienceDirect, Cochrane, Lilacs published until November 2019. The basic research strategy included "Spondylitis, Ankylosing" and "Interleukin-17". There was no language restriction. References to selected articles were reviewed to identify all relevant studies. Relevant data were independently extracted by two reviewers, and disagreement was resolved by a third reviewer. The data were collected from each study. The Newcastle-Ottawa Scale (NOS) was performed to blindly assess the methodological quality of the case-control studies by two reviewers.

## STATISTICAL ANALYSIS

The difference in serum IL-17 levels between the case and control groups and patients who were not active was compared by mean difference (MD) with 95% confidence intervals (95% CI), and the correlation between serum level and disease activity in AS was performed by CORs with 95% CI. The significance of clustered MDs and CORs was determined by the Z test and  $p < 0.05$  was considered statistically significant. Cochran's Q-statistic was considered significant with  $p < 0.05$  and I<sup>2</sup> tests were applied to determine heterogeneity. We quantified the effect of heterogeneity by using a recently developed measurement, namely,  $I^2 = 100\% \times (Q - df) / Q$ , with values of 25%, 50%, and 75% indicating low, moderate, and high heterogeneity,

respectively. The parameters of enrolled studies were mean  $\pm$  SD. The interquartile was calculated for the studies that did not have the standard deviation. All statistical analyses were carried out in RevMan software.

## RESULTS

### ELIGIBLE STUDIES SELECTED FOR META-ANALYSIS OF SERUM IL-17 LEVELS AND AS

The systematic review conducted in November 2020 of studies with IL-17 cytokine in serum of AS patients found 13,472 articles in Pubmed, ScienceDirect, Cochrane, and Lilacs databases (Figure 1). After the removal of duplicates, 12,498 articles remained. By reading titles and abstracts, the list was reduced to 69 articles. After analyzing the texts in full, 13 were selected for the meta-analysis, according to the inclusion criteria previously established.

The thirteen studies selected for meta-analysis contained a combined total of 1359 patients with AS and 746 healthy controls. Sample sizes in the studies ranged from 23 to 143 AS patients. All were published in English language except the study from Russia. The main characteristics of the studies are presented in Table 1.

### META-ANALYSIS RESULTS FOR SERUM LEVEL OF IL-17

Of the 13 articles selected, only 8 found statistical significance ( $p < 0.05$ ) of patients' IL-17 expression in relation to healthy controls (Figure 2). A total of 3 articles reported the correlation of IL-17 with disease activity Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) (Figure 3). Our meta-analysis observed the existence of heterogeneity in the 13 studies published in the random effect model used ( $I^2 = 99\%$ ,  $p = 0.00001$ ). As a main result, we observed that IL-17 expression is higher in patients than in controls (MD=9.75,

95% CI=6.43~13.07,  $p < 0.00001$ ). Nine studies found a correlation of BASDAI disease activity with serum levels of IL-17 (MD=14.59, 95% CI=7.73 ~ 21.45,  $p < 0.00001$ ).

We evaluated studies with patients with and without activity (MD=0.37, 95% CI=-2.19 ~ 2.93,  $p = 0.87$ ,  $I^2 = 0\%$ ) and before and after treatment (MD=46; 95% CI=-15.79 ~ 32.71,  $p = 0.02$ ,  $I^2 = 74\%$ ) (figure 4).

When the treatments were analyzed, the IL-17 expression of the untreated patients was higher than those treated with conventional drugs, with the average difference of MD=23.70, 95% CI = 4.60 ~ 42.79,  $P = 0.02$  and MD= 10.24, 95% CI = 3.32 ~ 17.17,  $p = 0.004$ , respectively. Patients using IL-17 did not show significance in relation to controls (Table 2).

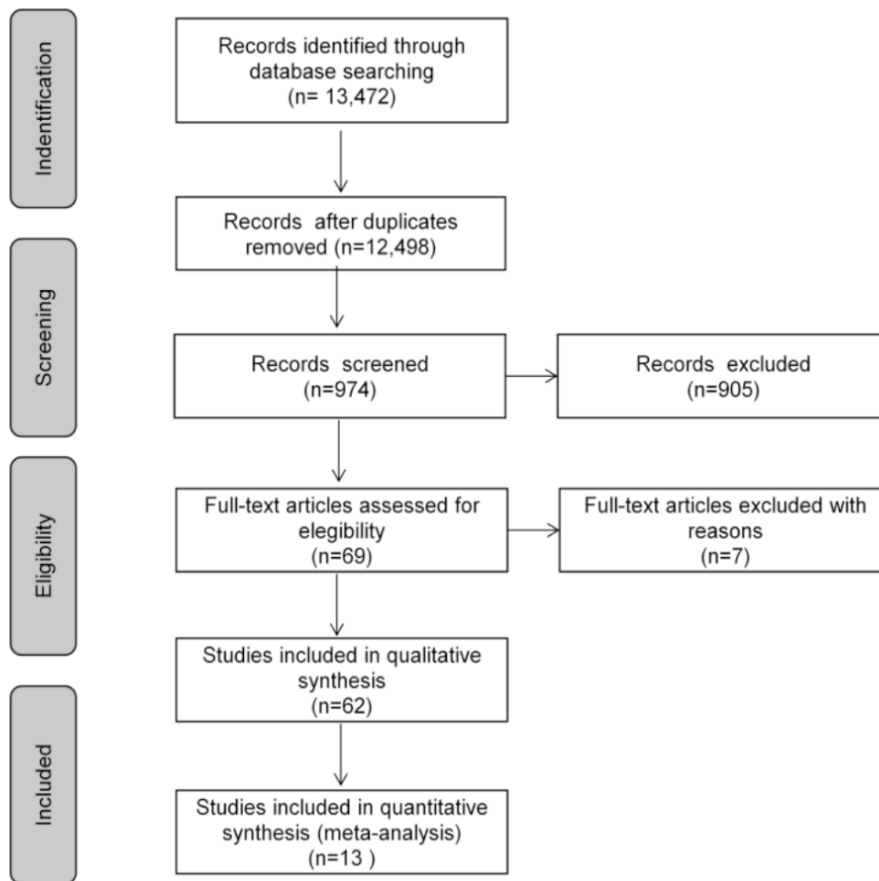

### SENSITIVITY ANALYSIS AND RISK OF PUBLICATION BIAS

Only four studies had a weight lower than 7% (figure 3). The risk of bias in the studies was performed in the RevMan program and according to the Newcastle-Ottawa Scale (NOS) criteria (Figure 5).

## DISCUSSION

In this study, we undertook a meta-analysis based approach to investigate the significance of elevated serum levels of IL-17 in AS development and the influence of conventional and anti-TNF drugs on cytokine expression. The serum IL-17 values in AS expression diverge greatly between articles. The studies showed that serum levels of IL-17 in AS patients were significantly higher than those of healthy controls. However, many case-control studies performed in different countries obtained conflicting results. This can be related to high heterogeneity index between studies.

Our main results found serum levels of IL-17 strikingly higher in AS patients than healthy controls, indicating that the cytokine

**Table 2.** Main meta-analysis results of the association between treatments and AS patients and controls

**Figure 5.** Detailed risk of bias results using the Newcastle-Ottawa Scale for Assessing Quality for observational studies

play a prominent role in AS pathogenesis. The subgroup analysis based on disease activity also demonstrated that serum IL-17 has significant association with elevated BASDAI in AS, demonstrating that IL-17 is correlated with disease activity.

Recent studies have investigated the IL23/IL-17 pathway and its influence on the pathogenesis of AS (GRAVALLESE; SCHETT, 2018; MEI et al., 2011; WENDLING, 2008). IL-17 is secreted by specialized Th17 subset of CD4+ T cells and is involved in host defense mechanisms against pathogens by inducing synthesis and secretion of pro-inflammatory molecules from fibroblasts, endothelial cells, and epithelial cells, including chemokines, antimicrobial peptides and matrix metalloproteinases (IWAKURA; ISHIGAME, 2006; KORN et al., 2007; REYNOLDS; ANGKASEKWINAI; DONG, 2010).

To investigate the contribution of treatment in influencing serum levels of IL-17, subgroup analyses were conducted with untreated patients, with conventional medication and anti-TNF. Our results indicated that mean difference of serum expression of interleukin IL-17 was significantly influenced by the treatment in use, which was higher in untreated patients than controls. Among patients who use conventional therapy, the expression was also significantly higher than controls. No statistical significance was observed for serum expression of anti-TNF-treated patients compared to controls. We also evaluated the influence before and after anti-TNF treatment and the studies do not exhibit any heterogeneity for the impact of the treatments on the outcome, which contributes with the results previously discussed.

Our results were similar to a study performed by Milanez and collaborators (2016), which investigated long-term influence of anti-TNF drugs in IL-23/IL-17 axis at 12 and 24-months of TNF blockade

in plasma. They found a strong correlation between IL-23 and IL-17A and ASDAS/PCR after anti-TNF therapy and concluded that the IL-23/IL-17 axis is not influenced by TNF blockade in AS patients despite clinical and inflammation improvements and NSAID intake.

The availability of new biological products targeting the IL-17/IL-23 axis has shown promising results in reducing the rate of radiographic progression in AS (MAGREY, M. N.; KHAN M. A., 2017). IL-17 antagonists secukinumab, ixekizumab, and brodalumab blocking the Th17 pathway by suppressing IL-17 act directly or through inhibition of Th17 cell differentiation (BABAIE, F. et al., 2018). Secukinumab is the first non-TNF alpha inhibitor agent licensed for AS. The studies point towards an efficacious role of IL-17A inhibition strategies targeting AS pathogenesis in a fundamental way with a good safety profile (DUBASH et al., 2019; BLAIR, et al., 2019). New studies involving larger patient groups are needed for the factors affecting serum IL-23/IL-17 levels in patients with AS (DEVECI, 2019).

It is very important to resolve the inconsistencies to increase the credibility of the meta-analysis conclusion. Limitations of the present meta-analysis must be acknowledged. First, evaluating only the cytokine of interest may substitute its contribution to the pathogenesis of the disease. Second, the treatment response or before and after treatment were carried out in a limited number of articles. Finally, many studies do not describe the treatments used by the patients or do not describe the mean concentration of the cytokines. Nevertheless, this is the first meta-analysis that identified the association of serum IL-17 level with AS and disease activity before and during treatment.

## CONCLUSION

This meta-analysis reveals that IL-17 is highly expressed in serum of patients with AS, and its amplitude is positively related to disease activity. IL-17 was significantly influenced by the treatment in use; however, the lack of significant difference in the expression of IL-17 in the treatment of patients taking anti-TNF proves that it does not interfere in this pathway. This clinical discovery provides implications for practice and research. Further studies are needed that include case-control trials and large population plus describe the medications that patients were using.
